Abstract

In this paper we give the boundary string field theory description of brane-antibrane systems. From the world-sheet action of brane-antibrane systems we obtain the tachyon potential and discuss the tachyon condensation exactly. We also find the world-volume action including the gauge fields. Moreover we determine RR-couplings exactly for non-BPS branes and brane-antibranes. These couplings are written by superconnections and correspond to $K^1(M)$ and $K^0(M)$ for the non-BPS branes and brane-antibranes, respectively. We also show that Myers terms appear if we include the transverse scalars in the boundary sigma model action.

1 Introduction

In recent years there has been a lot of work on tachyon physics [1]. In string theory tachyon fields naturally appear on the non-BPS branes [2, 3, 4, 5] and the brane-antibrane systems [6, 7, 8]. These studies of the dynamical aspects of non-BPS systems are very important to understand the vacuum structure of open string theory because we can always see the process of the vacuum transition from an unstable one to a stable one via the tachyon condensation. In the special case this process can be analyzed via the marginal deformation of conformal field theory [3, 4, 9, 10, 11]. However in the general situation the tachyon condensation is an off shell phenomenon. Thus we should use string field theories.

Historically the most famous string field theory-Witten's cubic string field theory-has been mainly used to compute the tachyon potential of bosonic branes, non BPS branes and brane-antibranes by the approximation which is called the level truncation (for example see [12]). This approximation is needed because generally in the process of the tachyon condensation many higher massive modes on a D-brane are excited, and we can not consider the infinite numbers of modes at the same time.

However quite recently another string field theory has been applied to the tachyon condensation. Some exact tachyon potentials and effective actions including both the tachyon and gauge fields were calculated [13, 14, 15, 16, 17, 18]. This is called background independent open string field theory (BIOSFT) or boundary string field theory (BSFT), which was first formulated by Witten [19]. This string field theory is based on the world-sheet sigma model action which is perturbed by the relevant operators on the boundary of disk. The strategy for the exact analysis is the following. If we put the profile of the tachyon field to the special form which makes the world-sheet sigma model action become free, then the massive modes on branes are not excited due to the renormalization of the world-sheet theory [13, 14]. Therefore the calculations including only the tachyon field are exact.

The boundary string field theory was first formulated for bosonic open string. Its superstring version is not known. However from the argument of the world-sheet supersymmetry and the boundary entropy the authors of [15] conjectured that the string field theory action is equal to the partition function. If this conjecture is correct, we can calculate more easily the string field theory action than in the bosonic case. In [15] by using this conjecture the effective action of non-BPS brane was calculated and this result was equal to the proposed form in several papers [20, 21, 22, 23] if we assume that the tachyon field is constant.

On the other hand only limited results for the effective action of the brane-antibrane have been obtained. For the results from on-shell scattering amplitude, see [24]. However the explicit form of the effective action is very important to know the dynamical aspects

of the tachyon condensation in the brane-antibrane systems. For example, if we want to discuss the noncommutative tachyon on the brane-antibrane, then the detailed form of the effective action is required [25]. These dynamical aspects of the brane-antibrane system such as its effective action can only be obtained by the off-shell calculations. Especially the boundary string field theory is suitable for investigating the general structure of the effective action exactly.

Therefore one of the purpose of this paper is to study the effective action of the brane-antibrane system in boundary string field theory. Indeed, we obtain *exact* results for the tachyon condensation. Especially we show that by considering the special profile of tachyons (kink or vortex) lower dimensional D-branes are produced and these tensions are equal to the known values exactly. We also discuss the general non-abelian cases and show that so called Atiyah-Bott-Shapiro (ABS) construction [26] naturally appears in the boundary string field theory.

However if we include the gauge field, the tachyon on the brane-antibrane couples to two kinds of the gauge fields in the bi-fundamental representation. Therefore there is no choice of the profiles of the tachyon and the gauge field to make the world-sheet action free. And it is difficult to obtain the exact effective action for the tachyons and gauge fields. This is different from abelian non-BPS case [15] (in this case the tachyon does not couple to the gauge field because the tachyon is in the $U(1)$ adjoint representation). However it is possible to calculate several lower terms in the α' expansion. And we can also discuss the general form of the effective action. Indeed this general form is consistent with the argument on the noncommutative solitons [25].

Above arguments are limited to the effective action for NSNS sector. However the boundary string field theory has the remarkable property that the on-shell RR closed vertex can be inserted, while it is difficult for the cubic string field theory. Moreover in the boundary string field theory we can formally incorporate the gauge fields at any order, while in the cubic theory we can introduce the gauge fields only by the perturbation. If one notices that the boundary interactions for the gauge field strengthes are similar to the RR-couplings of BPS D-branes represented by the Chern character, one expects that in the boundary string field theory RR-couplings of the non-BPS branes and brane-antibranes is computable *exactly*. Indeed this expectation is true. Therefore in this paper we give the most general coupling forms in the case of non-BPS branes and of brane-antibrane systems. These are represented by the so called *superconnection* [27], which was conjectured in [28, 29] in the case of brane-antibranes. We can also show that the RR coupling of non-BPS branes has the structure of the superconnection. In mathematics it is known that the charge which is represented by Chern character of a superconnection is equivalent to K-theory charge. This means that the RR-coupling of brane-antibranes and non-BPS branes corresponds to $K^0(M)$ and $K^1(M)$ respectively. Therefore this gives another evidence of K-theory classification of D-brane charges [30, 28, 31].

The plan of the paper is the following.

In section 2 we review the boundary string field theory for non-BPS branes and present the world-sheet action for the brane-antibrane system. We justify this world-sheet action by showing that with putting the tachyon field to zero the partition function becomes the sum of two DBI actions, which is one for a brane and the other for an antibrane.

In section 3 we study exact tachyon condensations for special profiles of the tachyon and show that the tensions of lower D-branes which are produced after the tachyon condensation are equal to known values in general situations and we relate these tachyon profiles to Atiyah-Bott-Shapiro construction.

In section 4 we calculate RR couplings for brane-antibranes and non-BPS D-branes by boundary string field theory. We also discuss that these forms are written by the superconnections, and we relate these to K-theory groups. In the last subsections we generalize these couplings to the couplings including noncommutative transverse scalars, which is called Myers term [32].

In section 5 we calculate the effective action for NSNS sector. We show that the form of the action is the sum of the DBI actions multiplied by the tachyon potential and that this action is consistent with the argument of the noncommutative soliton. We also calculate several lower terms in the α' expansion.

In appendix we summarize the notations and spinor formulas mainly for the calculation of RR-couplings.

2 World-Sheet Action of Brane-Antibrane System

Recently using background independent open string field theory several effective actions has been calculated exactly in a certain sense [13, 14, 15]. This string field theory (from now on we call this BSFT) was first considered by Witten in the bosonic open string field theory [19]. In that paper the open string field action was defined by extending Batalin-Vilkovisky (BV) formalism to that for open-string fields. The solution of this string field master equation was given by [33]:

$$S = (\beta^i(\lambda) \frac{\partial}{\partial \lambda^i} + 1)Z, \quad (2.1)$$

where S is the string field action, Z is the partition function, λ^i is one dimensional coupling of sigma model (i.e. target space field) and $\beta^i(\lambda)$ is beta function of it.

This is for bosonic open string field theory. The BV-like formulation of background independent superstring field theory has not been found until now. However the relation between S and Z in (2.1) can be generalized to the supersymmetric version. Some years ago Tseytlin et.al.[34, 35] calculated several partition functions including only the gauge fields and they confirmed that partition functions were equal to the effective actions

constructed by calculating S-matrix perturbatively in supersymmetric case (not in bosonic case). Moreover they conjectured that this partition function can be identified with *off shell* string field action. In [15] they extended these interpretations to the full open string field theory including tachyons.

Therefore in this paper we expect that the same relation holds not only for non-BPS branes but also for brane-antibrane systems:

$$S = Z. \quad (2.2)$$

Below we propose a brane-antibrane sigma model action and calculate the string field action. This sigma model action is the extension of non-BPS brane's one, thus before giving this we first review non-BPS brane's one[15, 36].

The partition function is defined by:

$$Z = \int DX D\psi D\eta \exp[-I(X, \psi, \eta)]. \quad (2.3)$$

In this definition the action of the σ model I is:

$$I = I_0 + I_B, \quad (2.4)$$

$$I_0 = \frac{1}{4\pi} \int_{\Sigma} d^2z [\partial_z X^\mu \partial_{\bar{z}} X_\mu + \psi^\mu \partial_{\bar{z}} \psi_\mu + \tilde{\psi}^\mu \partial_z \tilde{\psi}_\mu], \quad (2.5)$$

$$I_B = \int_{\partial\Sigma} d\tau d\theta [-\mathbf{\Gamma} D_\theta \mathbf{\Gamma} + \frac{1}{\sqrt{2\pi}} T(\mathbf{X}) \mathbf{\Gamma} - i D_\theta \mathbf{X}^\mu A_\mu(\mathbf{X})]. \quad (2.6)$$

where the superspace representation in the boundary theory is defined by: ⁴

$$\begin{cases} \mathbf{X}^\mu &= X^\mu + 2i\theta\psi^\mu, \\ \mathbf{\Gamma} &= \eta + \theta F, \\ D_\theta &= \frac{\partial}{\partial\theta} + \theta \frac{\partial}{\partial\tau}. \end{cases} \quad (2.7)$$

If one writes I_B in the component form and integrate out the auxiliary field F , then it becomes:

$$I_B = \int_{\partial\Sigma} d\tau [\frac{1}{8\pi} T(X)^2 + \eta\dot{\eta} + i\sqrt{\frac{2}{\pi}} \psi^\mu \eta \partial_\mu T - i\dot{X}^\mu A_\mu + 2iF_{\mu\nu} \psi^\mu \psi^\nu]. \quad (2.8)$$

This is the world-sheet action for a non-BPS brane.

The superfield $\mathbf{\Gamma}$ corresponds to the internal degrees of the freedom of non-BPS branes which is equal to 2×2 matrices $1, \sigma_2$ (Pauli matrix) [5, 1]. This $\mathbf{\Gamma}$ field description is first given by Witten [28] and Harvey et.al. proposed that this action (2.8) describes non-BPS branes in [37].

⁴In this paper we set α' to 2.

The tachyon field $T(\mathbf{X})$ is gauge-transformed in the $U(1)$ adjoint representation (that is equal to the gauge singlet), thus this action is gauge invariant without $\mathbf{\Gamma}$ being gauge transformed. This makes $T(\mathbf{X}), \mathbf{\Gamma}$ decoupled from the gauge field, which fact appears in the (2.6). Therefore if one exponentializes the action I and performs the path-integration in the approximation of neglecting the third term of (2.8), the partition function $Z(=S)$ becomes the simple structure which is the product of the DBI action and tachyon potential $\exp(-\frac{1}{4}T^2)$ [20, 22, 23, 14, 15].

However if we consider non-abelian non-BPS D-branes, the tachyon field couples to the gauge fields, its action is more complicated than $U(1)$ case and the calculation of effective action is difficult. Non-abelian action was proposed in [36]:

$$I_B = \int_{\partial\Sigma} d\tau d\theta [-\bar{\Delta} D_\theta \Delta - \mathbf{\Gamma} D_\theta \mathbf{\Gamma} + \bar{\Delta} \{ -\frac{1}{\sqrt{2\pi}} \mathbf{\Gamma} T(\mathbf{X}) + i A_\mu(\mathbf{X}) D\mathbf{X}^\mu \} \Delta], \quad (2.9)$$

where $T(\mathbf{X})$ is $N \times N$ matrix in the case of N non-BPS D-branes, Δ is complex fermionic superfield which couples to the gauge field in the fundamental representation.

Next, we want to extend this action to the brane-antibrane system⁵, which contains tachyons and is unstable. Before considering the world-sheet action, we should be reminded of the characteristic properties of this system (For a review, see [1]). First, a brane-antibrane system has two kinds of vector multiplets (gauge fields and GSO even fermions). One lives in D-brane, another in anti D-brane. Second, the tachyons and GSO odd fermions come from the open strings between a D-brane and an anti D-brane. In Type II theories open strings have the orientation, thus the D-brane and the anti D-brane have two kinds of real tachyon fields and we can represent these by a complex tachyon field which belongs to the bi-fundamental representation. Third, this system is essentially non-abelian (this contains at least two branes in one pair system) and this contains the Chan-Paton factors. Especially in the one pair case, the Chan-Paton factors are represented by 2×2 matrices (identity matrix and Pauli matrices $(\sigma_1, \sigma_2, \sigma_3)$). The identity matrix represents the freedom of the total sum of gauge fields of the system. The matrix σ_3 represents the freedom of the relative difference of gauge fields and σ_1, σ_2 the ones of tachyons. These are the main properties of brane-antibrane systems.

It is famous that these are related to non-BPS D-branes by the “descent relation” conjectured by Sen [1, 4, 38]. Therefore we expect that the world-sheet action is very similar to the one of non-BPS branes. Naively the real tachyon field $T(X)$ in (2.6) is extended to the complex field $T(\mathbf{X}), \bar{T}(\mathbf{X})$ which is gauge-transformed as follows:

$$T(\mathbf{X}) \rightarrow e^{i\lambda_1(\mathbf{X})} T(\mathbf{X}) e^{-i\lambda_2(\mathbf{X})}, \quad (2.10)$$

where λ_1, λ_2 are arbitrary functions of \mathbf{X} . The sigma model action for the non-BPS D-

⁵In this paper we mainly consider one pair brane-antibrane case. About the generic configuration of brane-antibrane system (m D-brane + n anti D-brane) we comment at several points.

brane (2.6) respects gauge-symmetry⁶ and world-sheet supersymmetry, thus in the case of the brane-antibrane it is natural to require these symmetries. From these considerations we propose that the following action defines the $D9-\overline{D9}$ action in BSFT (One for $Dp-\overline{Dp}$ is simply obtained by T-duality).

$$I = I_0 + I_B, \quad (2.11)$$

$$I_0 = \frac{1}{4\pi} \int_{\Sigma} d^2z [\partial_z X^\mu \partial_{\bar{z}} X_\mu + \psi^\mu \partial_{\bar{z}} \psi_\mu + \tilde{\psi}^\mu \partial_z \tilde{\psi}_\mu], \quad (2.12)$$

$$I_B = \int_{\partial\Sigma} d\tau d\theta [-\bar{\Gamma}(D_\theta - iA_\mu^{(-)}(\mathbf{X})D_\theta \mathbf{X}^\mu)\Gamma + \frac{1}{\sqrt{2\pi}}\bar{\Gamma}T(\mathbf{X}) + \frac{1}{\sqrt{2\pi}}\bar{T}(\mathbf{X})\Gamma - \frac{i}{2}D_\theta \mathbf{X}^\mu A_\mu^{(+)}(\mathbf{X})]. \quad (2.13)$$

If we write I_B in the component form and integrate out the auxiliary fields F, \bar{F} in Γ and $\bar{\Gamma}$:

$$I_B = \int_{\partial\Sigma} d\tau [\bar{\eta}\dot{\eta} + 2i\bar{\eta}\eta\psi^\mu\psi^\nu F_{\mu\nu}^{(-)} - i\bar{\eta}\eta\dot{X}^\mu A_\mu^{(-)} - i\sqrt{\frac{2}{\pi}}\bar{\eta}\psi^\mu D_\mu T + i\sqrt{\frac{2}{\pi}}\psi^\mu\eta\overline{D_\mu T} + \frac{1}{2\pi}\bar{T}T - \frac{i}{2}\dot{X}^\mu A_\mu^{(+)} + i\psi^\mu\psi^\nu F_{\mu\nu}^{(+)}], \quad (2.14)$$

where we have employed the following definition:

$$\begin{cases} A_\mu^{(\pm)} &= A_\mu^{(1)} \pm A_\mu^{(2)}, \\ D_\mu T &= \partial_\mu T - iA_\mu^{(-)}T, \\ F_{\mu\nu}^{(1),(2)} &= \partial_\mu A_\nu^{(1),(2)} - \partial_\nu A_\mu^{(1),(2)}. \end{cases} \quad (2.15)$$

The field Γ is gauge-transformed in the bi-fundamental representation which is same as (2.10). This fact forces the first term in (2.13) to be gauged. This is crucial difference from the non-BPS brane case (2.6). This prescription is usual in Type I or Heterotic non-linear sigma model action (for example see the section 12.3 in [39]).

On the other hand, if we construct the most general one-dimensional *renormalizable* action which is written by superfields $\Gamma, \bar{\Gamma}$ and \mathbf{X} , then this action coincides with (2.13) up to the arbitrary real function $g(\mathbf{X})$ in front of the first term of (2.13). This may be confusing, because it looks as if the new real scalar field $g(\mathbf{X})$ appeared on the brane-antibrane. However, this $g(\mathbf{X})$ can be eliminated by the redefinition of $\Gamma, T(\mathbf{X})$ and $A_\mu^\pm(\mathbf{X})$. Therefore this $g(\mathbf{X})$ is a redundant two-dimensional sigma model coupling, and even if we set $g(\mathbf{X})$ to 1, the renormalizability is respected. At any rate eq.(2.13) is the renormalizable action. We will use this fact in section 5.

⁶Strictly speaking this symmetry is not two dimensional gauge symmetry but non-linear global symmetry. However it is famous in usual sigma model(Type I, Heterotic) that world-sheet global symmetry corresponds to target space gauge symmetry

From this action, we can calculate the effective action of the brane-antibrane system. Especially we are interested in the form of NSNS effective action of the brane-antibrane system, which corresponds to the Dirac-Born-Infeld (DBI) part of BPS D-brane action, because the explicit form of this effective action is not known as much as non-BPS one (In the non-BPS case the action is more familiar than the brane-antibrane. This is proposed in several papers [20, 22, 23]).

Since above arguments of constructing brane-antibrane action are too heuristic, we have to confirm that this action describes the brane-antibrane system correctly from several point of view. In this paper, we confirm three nontrivial checks before calculating the full NSNS action of the brane-antibrane as follows:

- With setting $T(X)$ to 0 in (2.13) we reproduce the sum of the DBI action of two kinds of gauge fields.
- By considering the tachyon condensation without the gauge fields by BSFT we check the descent relation between the non-BPS D-brane and the brane-antibrane.
- We reproduce *exactly* the RR couplings of the brane-antibranes conjectured in [29] which are represented by superconnection formula [27].

At first sight the first fact looks false because even if we set $T(X) = 0$, it is likely that massive modes which fly between a D-brane and an antiD-brane modify the sum of DBI actions. However this effect comes from open string one loop effect (cylinder amplitude) and in the disk amplitude this effect does not cause any modification.

Now we check the first fact. The second and the third fact will be checked in the section 3 and 4, respectively, and finally in the section 5 we calculate the NSNS action. The path integral representation of the partition function is given by (2.3). First we split Z into two dimensional part (internal of disk) and one dimensional part (boundary of the disk):

$$Z = \int DX D\psi \exp[-I_0(X, \psi)] \int D\eta D\bar{\eta} \exp[-I_B(X, \psi, \eta, \bar{\eta})]. \quad (2.16)$$

In open string NS sector $\psi(\tau)$ obeys the anti-periodic boundary condition so that $\psi(\tau)$ has half-integer Fourier modes. Then $\eta(\tau)$ and $\bar{\eta}(\tau)$ should also obey the anti-periodic boundary condition in order for (2.14) to be locally well defined.

Here we integrate $\eta(\tau)$ and $\bar{\eta}(\tau)$ first. The path integral of $\eta(\tau)$ and $\bar{\eta}(\tau)$ is defined on the circle, which corresponds to one loop partition function. Therefore transforming this path integral to Hamiltonian formalism, η and $\bar{\eta}$ are quantized and from (2.14) these obey the usual canonical quantization condition:

$$\{\eta, \bar{\eta}\} = 1. \quad (2.17)$$

By using canonical quantization method of η and $\bar{\eta}$, the partition function Z becomes as follows:

$$\begin{aligned}
Z = & \int DX D\psi \exp[-I_0(X, \psi)] \\
& \times \text{Tr P exp} \int_{-\pi}^{\pi} d\tau \left[i \frac{[\bar{\eta}, \eta]}{2} \dot{X}^{\mu} A_{\mu}^{(-)}(X) - 2i \frac{[\bar{\eta}, \eta]}{2} \psi^{\mu} \psi^{\nu} F_{\mu\nu}^{(-)}(X) + i \sqrt{\frac{2}{\pi}} \bar{\eta} \psi^{\mu} D_{\mu} T(X) \right. \\
& \left. - i \sqrt{\frac{2}{\pi}} \psi^{\mu} \eta \overline{D_{\mu} T(X)} - \frac{1}{2\pi} \bar{T}(X) T(X) + \frac{i}{2} \dot{X}^{\mu} A_{\mu}^{(+)}(X) - i \psi^{\mu} \psi^{\nu} F_{\mu\nu}^{(+)}(X) \right], \quad (2.18)
\end{aligned}$$

where “P” represents the path ordering and “Tr”(trace) implies that we should sum expectation values in two state Hilbert space:

$$\begin{aligned}
\eta | \downarrow \rangle &= 0 \quad , \quad \bar{\eta} | \downarrow \rangle = | \uparrow \rangle, \\
\eta | \uparrow \rangle &= | \downarrow \rangle \quad , \quad \bar{\eta} | \uparrow \rangle = 0.
\end{aligned} \quad (2.19)$$

When we construct Hamiltonian from Lagrangian, we set the operator ordering by antisymmetrization of η and $\bar{\eta}$.

This is a consequence from the quantum mechanics, but at a first glance it is strange. We said that classical fields $\eta, \bar{\eta}$ obey anti-periodic boundary conditions and have half-integer modes. Therefore they do not have zero-modes. However if we use Hamiltonian formalism, τ dependence of $\eta, \bar{\eta}$ drops out and it looks like that only zero modes remain. This is confusing. Yet if we perform the path integral simply by the perturbation using $\eta, \bar{\eta}$ Green function with anti-periodic boundary condition:

$$\langle \eta(\tau) \bar{\eta}(\tau') \rangle = \frac{1}{2} \epsilon(\tau - \tau') = \frac{1}{\pi} \sum_{r \in \mathbf{Z} + \frac{1}{2} > 0} \frac{\sin\{r(\tau - \tau')\}}{r}, \quad (2.20)$$

$$\epsilon(\tau) \equiv \begin{cases} 1 & (\tau > 0) \\ 0 & (\tau = 0) \\ -1 & (\tau < 0) \end{cases}, \quad (2.21)$$

then we can check order by order that path integral representation (2.16) is equal to (2.18). However note that this identity holds only for $\epsilon(0) = 0$ regularization.

Here we can check that the operator commutation and anti-commutation relation of $\bar{\eta}, \eta, [\bar{\eta}, \eta]$ are same as that of Pauli matrix, $\sigma_+, \sigma_-, \sigma_3$ (where $\sigma_{\pm} \equiv \frac{1}{2}(\sigma_1 \pm i\sigma_2)$). Therefore we can replace $\bar{\eta}, \eta, [\bar{\eta}, \eta]$ by $\sigma_+, \sigma_-, \sigma_3$, respectively.

In that form Z becomes:

$$Z = \int DX D\psi \exp[-I_0(X, \psi)] \times \text{Tr P exp} \int_{-\pi}^{\pi} d\tau M(\tau), \quad (2.22)$$

where

$$M(\tau) = \begin{pmatrix} i \dot{X}^{\mu} A_{\mu}^{(1)} - 2i \psi^{\mu} \psi^{\nu} F_{\mu\nu}^{(1)} - \frac{1}{2\pi} T \bar{T} & i \sqrt{\frac{2}{\pi}} \psi^{\mu} D_{\mu} T \\ -i \sqrt{\frac{2}{\pi}} \psi^{\mu} \overline{D_{\mu} T} & i \dot{X}^{\mu} A_{\mu}^{(2)} - 2i \psi^{\mu} \psi^{\nu} F_{\mu\nu}^{(2)} - \frac{1}{2\pi} \bar{T} T \end{pmatrix}. \quad (2.23)$$

This is one expression of the brane-antibrane partition function. Furthermore this form is able to be extended to the generic configuration of the brane-antibrane system (m D-branes and n antiD-branes) because in that case we have only to replace $A_\mu^{(1)}(X)$, $A_\mu^{(2)}(X)$ and $T(X)$ in (2.23) with $m \times m$, $n \times n$ and $m \times n$ matrices, respectively, while the expression (2.22) has one fault that the gauge symmetry and the world-sheet supersymmetry cannot be seen explicitly. We could not find (2.13) type action in the case of the non-abelian brane-antibrane system.

Then we go back to the original question. That is “With setting $T(X)$ to 0 in (2.13) can we reproduce the sum of the DBI actions ?” If one sets $T(X)$ to 0 in (2.23), the off-diagonal part vanishes and the diagonal part remains. In this case Z becomes as follows:

$$\begin{aligned}
Z &= \int DX D\psi \exp[-I_0(X, \psi)] \\
&\times \text{Tr P exp} \int_{-\pi}^{\pi} d\tau \begin{bmatrix} i\dot{X}^\mu A_\mu^{(1)} - 2i\psi^\mu \psi^\nu F_{\mu\nu}^{(1)} & 0 \\ 0 & i\dot{X}^\mu A_\mu^{(2)} - 2i\psi^\mu \psi^\nu F_{\mu\nu}^{(2)} \end{bmatrix} \\
&= \int DX D\psi \exp[-I_0(X, \psi)] \\
&\times \sum_{k=1}^2 \text{Tr P exp} \int_{-\pi}^{\pi} d\tau [i\dot{X}^\mu A_\mu^{(k)} - 2i\psi^\mu \psi^\nu F_{\mu\nu}^{(k)}]. \tag{2.24}
\end{aligned}$$

This defines the sum of the NSNS action for $A_\mu^{(1)}(X)$, $A_\mu^{(2)}(X)$. In general form of $A_\mu(X)$ this integration is only perturbatively possible, while in the approximation that $F_{\mu\nu}$ and the metric $g_{\mu\nu}$ are constant the integration is exact [40, 35, 34] and Z becomes as follows:

$$Z = T_9 \int d^{10}x \left[\sqrt{-\det\{g_{\mu\nu} + 4\pi(B_{\mu\nu} + F_{\mu\nu}^{(1)})\}} + \sqrt{-\det\{g_{\mu\nu} + 4\pi(B_{\mu\nu} + F_{\mu\nu}^{(2)})\}} \right], \tag{2.25}$$

where T_9 is tension of a BPS D9-brane. Here we have replaced $F^{(i)}$ with $F^{(i)} + B$ using the Λ symmetry, $F_{\mu\nu}^{(i)} \rightarrow F_{\mu\nu}^{(i)} + (d\Lambda)_{\mu\nu}$ and $B_{\mu\nu} \rightarrow B_{\mu\nu} - (d\Lambda)_{\mu\nu}$ for later convenience. This is the desired result ($Dp - \overline{Dp}$ case is obtained by T-duality).

3 Exact Tachyon Condensation on Brane-Antibrane Systems

Here we investigate the tachyon condensation on brane-antibrane systems. It is obvious that the condensation of a constant tachyon field leads to the decay into the closed string vacuum $S = 0$. The more interesting process is the condensation of topologically nontrivial configurations of the tachyon field. According to the Sen’s conjecture [3, 28] a codimension n configuration on Dp -branes generally produces $D(p - n)$ -branes. As we

will see below, from the tractable free field calculations in BSFT we can describe such a tachyon condensation exactly. We can perform explicit computations in parallel with that for non-BPS D-branes discussed in [15]. A crucial difference is that we can allow the vortex-type configurations since the tachyon field on a brane-antibrane system is a complex scalar field.

Note also that even though our regularization throughout in this paper is based on “ ϵ -prescription” used in [34, 35, 36, 41], the result does not change if we use the point splitting regularization as in [19, 15].

First let us consider the condensation of the vortex-type tachyon field on a single $Dp - \overline{Dp}$. From the viewpoint of the boundary conformal field theory (BCFT) one can describe the condensation as a marginal deformation [10, 11] only. In BSFT defined by the boundary action (2.14), we can also handle a relevant perturbation with two real parameters u_i ($i = 1, 2$) :

$$T(X) = \frac{1}{2}(iu_1X_1 + u_2X_2). \quad (3.1)$$

Here we have set the gauge fields to zero. One can show that any tachyon fields of the form $T(X) = a + \sum_{\mu=0}^p b_\mu X^\mu$, ($a, b_\mu \in \mathbf{C}$) can be put into the form (3.1) by a Poincaré transformation and the $U(1)$ gauge transformation.

Note also that this perturbation can be treated as a free boundary interaction and therefore the mixings with the other open string modes are avoided for all values of u_i (see also [14, 15]).

For non-zero u_i this represents a vortex which is a codimension two configuration along the x^1 - x^2 plane. If $u_1 = 0$ or $u_2 = 0$, then this corresponds to a kink configuration. This fact is easy to see if one notes that the bosonic zero mode structure of BSFT on the $Dp - \overline{Dp}$ behaves as

$$S \sim e^{-|T(x_1, x_2)|^2} = e^{-\frac{1}{4}(u_1x_1)^2 - \frac{1}{4}(u_2x_2)^2}, \quad (3.2)$$

which shows the tachyon condensation leads to the desired localized configuration for large u_1 and u_2 .

In the presence of this boundary interaction the correlation functions in the NS-sector are given by [15]

$$G_B(\tau - \tau', y_i, \epsilon) = \langle X^i(\tau) X^i(\tau') \rangle = 2 \sum_{m \in \mathbf{Z}} \frac{1}{|m| + y_i} e^{im(\tau - \tau') - \epsilon|m|}, \quad (3.3)$$

$$G_F(\tau - \tau', y_i, \epsilon) = \langle \psi^i(\tau) \psi^i(\tau') \rangle = -\frac{i}{2} \sum_{r \in \mathbf{Z} + \frac{1}{2}} \frac{r}{|r| + y_i} e^{ir(\tau - \tau') - \epsilon|r|}, \quad (i : \text{no sum}) \quad (3.4)$$

where we have defined

$$y_i = u_i^2. \quad (3.5)$$

Note that in the above expression we have used “ ϵ -regularization” discussed in [34, 35, 36, 41].

On the other hand the BSFT action $S(=Z)$ including the boundary interaction can be computed by differentiating with respect to y_1 and y_2 , respectively

$$\begin{aligned}\frac{\partial}{\partial y_i} \log S &= -\frac{1}{8\pi} \int_0^{2\pi} d\tau \langle X^i(\tau) X^i(\tau) - 4\psi^i(\tau) \frac{1}{\partial_\tau} \psi^i(\tau) \rangle \\ &= -\frac{1}{2} [G_B(0, y_i, \epsilon) - G_B(0, 2y_i, \epsilon/2)].\end{aligned}\quad (3.6)$$

The difference of the correlators $G_B(0, y_i, \epsilon) - G_B(0, 2y_i, \epsilon/2)$ is given in the limit of $\epsilon \rightarrow 0$ by

$$\begin{aligned}\lim_{\epsilon \rightarrow 0} [G_B(0, y, \epsilon) - G_B(0, 2y, \epsilon/2)] &= 4 \sum_{m \geq 1} \left(\frac{1}{m+y} e^{-\epsilon m} - \frac{1}{m+2y} e^{-\frac{\epsilon}{2} m} \right) + \left(\frac{2}{y} - \frac{1}{y} \right) \\ &= \lim_{\epsilon \rightarrow 0} \left[4 \sum_{m \geq 1} \frac{1}{m} (e^{-\epsilon m} - e^{-\frac{\epsilon}{2} m}) \right] + 4 \sum_{m \geq 1} \left(\frac{1}{m+y} - \frac{1}{m} \right) - 4 \sum_{m \geq 1} \left(\frac{1}{m+2y} - \frac{1}{m} \right) + \left(\frac{2}{y} - \frac{1}{y} \right) \\ &= -4 \log 2 - \left(4 \frac{d}{dy} \log \Gamma(y) + \frac{2}{y} + 4\gamma \right) + \left(2 \frac{d}{dy} \log \Gamma(2y) + \frac{1}{y} + 4\gamma \right),\end{aligned}\quad (3.7)$$

where we have used the following formulae:

$$\sum_{m \geq 1} \frac{1}{m} e^{-\epsilon m} = -\log \epsilon + O(\epsilon), \quad (3.8)$$

$$\frac{d}{dy} \log \Gamma(y) = -\frac{1}{y} + \sum_{m \geq 1} \frac{y}{m(m+y)} - \gamma \quad (\gamma: \text{Euler's constant}). \quad (3.9)$$

Then it is easy to integrate eq.(3.6) and we obtain S up to the overall normalization S_0 :

$$\begin{aligned}S(y_1, y, 2) &= S_0 Z(y_1) Z(y_2), \\ Z(y) &= 4^y \frac{Z_1(y)^2}{Z_1(2y)},\end{aligned}\quad (3.10)$$

where Z_1 is a function peculiar to BSFT [19],

$$Z_1(y) = \sqrt{y} e^{\gamma y} \Gamma(y). \quad (3.11)$$

The original $Dp - \overline{Dp}$ corresponds to $u_i = 0$ and at this value the action is divergent since the world-volume of the brane is non-compact :

$$S(Dp - \overline{Dp}) \rightarrow S_0 \frac{2}{\sqrt{y_1 y_2}} \quad (y_i \rightarrow 0). \quad (3.12)$$

In the above computation the parameters y_i play the role of cutoffs and are equivalent to a regularization by compactification $X^i \sim X^i + R_i$ as

$$\frac{R_1 R_2}{2\pi} \sim \int_0^\infty \frac{dx^1 dx^2}{2\pi} e^{-\frac{1}{4} y_1 (x^1)^2 - \frac{1}{4} y_2 (x^2)^2} = \frac{2}{\sqrt{y_1 y_2}}. \quad (3.13)$$

Let us now condense the tachyon field. Only when the tachyon is infinitely condensed $u_i = \infty$, the conformal invariance is restored, which implies that the equation of motion is satisfied, because $Z(y)$ is a monotonically decreasing function of y . Therefore there exist three decay modes $(u_1, u_2) = (\infty, 0)$, $(0, \infty)$, or (∞, ∞) . The first two cases represent the kink configurations and we expect a non-BPS $D(p-1)$ -brane will be generated at $x^1 = 0$ or $x^2 = 0$, respectively. This speculation is verified if one computes the tension (for $(u_1, u_2) = (\infty, 0)$) and see that the correct value⁷ is reproduced as follows

$$\frac{T_{Dp-\bar{D}p}}{T_{D(p-1)}} = \frac{S(0, 0) \cdot (R_1)^{-1}}{S(\infty, 0)} = \frac{1}{2\pi}, \quad (3.14)$$

where $T_{Dp-\bar{D}p}$ and $T_{D(p-1)}$ denotes the tension of a $Dp-\bar{D}p$ and a non-BPS $D(p-1)$ -brane, respectively; we have also used the fact

$$Z(y) \rightarrow \sqrt{2\pi} \quad (y \rightarrow \infty). \quad (3.15)$$

More intuitive way to see the generation of a non-BPS $D(p-1)$ -brane is to discuss the boundary interaction (2.14). Let us shift the original tachyon field by a real constant T_0 along x^1 as follows:

$$T(X) = \frac{1}{2}T_0 + \frac{i}{2}u_1X_1. \quad (3.16)$$

Then the boundary interaction (2.14) after the condensation of the tachyon field (3.16) becomes

$$I_B = \int_{\partial\Sigma} d\tau [\bar{\eta}\dot{\eta} + \frac{1}{\sqrt{2\pi}}u_1\psi^1(\eta - \bar{\eta}) + \frac{1}{8\pi}T_0^2 + \frac{1}{8\pi}u_1(X^1)^2 + \dots], \quad (3.17)$$

where the new tachyon field T_0 depends only on X^a ($a = 0, 2, \dots, p$). From this expression it is easy to see that in the limit of $u_1 \rightarrow \infty$ we can set $\eta = \bar{\eta}$ after we perform the path integral of the fermion ψ^1 . Then the term in \dots which depends on $A_{\mu\nu}^{(-)}$ vanishes because it is proportional to $\bar{\eta}\eta \sim 0$. On the other hand, the gauge field $A_\mu^{(+)}$ is not sensitive to the tachyon condensation except that the element $A_1^{(+)}$ is no longer a gauge field but a transverse scalar field since the boundary condition along x^1 becomes Dirichlet. Thus the final boundary action after integrating out the fields X^1, ψ^1 is identified with that of a non-BPS $D(p-1)$ -brane (2.8).

Next we turn to the last case $(u_1, u_2) = (\infty, \infty)$. This corresponds to the vortex-type configuration and a BPS $D(p-2)$ -brane is expected to be generated at $(x^1, x^2) = (0, 0)$. This fact is also checked by comparing the tension as follows:

$$\frac{T_{Dp-\bar{D}p}}{T_{D(p-2)}} = \frac{S(0, 0) \cdot (R_1 R_2)^{-1}}{S(\infty, \infty)} = \frac{1}{4\pi^2}, \quad (3.18)$$

⁷Note that we set $\alpha' = 2$ and that the tension of a non-BPS Dp -brane is larger than that of a BPS D -brane by the factor $\sqrt{2}$.

matching with the known result. Also note that this configuration has no tachyonic modes as desired. Indeed constant shifts of the original tachyon field (3.1) are equivalent to the shift of the position where the D-brane is generated.

It is also interesting to consider multiple branes and antibranes. This can be represented by the Chan-Paton factors. Following [28] let us consider 2^{k-1} pairs of brane-antibranes and condense the tachyon field

$$T(X) = i \frac{u}{2} \sum_{\mu=1}^{2k} \Gamma^\mu X_\mu, \quad (3.19)$$

where Γ^μ denote $2^{k-1} \times 2^{k-1}$ Γ -matrices in $2k$ dimension and the extra factor i is due to our convention of Γ -matrices.

These configurations carry K-theory charges known as Atiyah-Bott-Shapiro construction [26] and a BPS $D(p-2k)$ -brane is expected to be generated. This fact will be more explicit by investigating the RR couplings in the next section. The verification of the correct tension is the same as in the previous cases if one notes that the additional factor 2^{k-1} from the Chan-Paton factor should be included. Similarly one can also see the condensation of the tachyon field

$$T(X) = i \frac{u}{2} \sum_{\mu=1}^{2k-1} \Gamma^\mu X_\mu, \quad (3.20)$$

on 2^{k-1} pairs of brane-antibranes produces a non-BPS $D(p-2k+1)$ -brane.

In this way we have obtained all decay modes which can be handled in BSFT by free field calculations and these are all consistent with the BCFT results and K-theoretic arguments. The incorporation of B -field (or equally $F^{(+)}$) can also be performed by free field calculations and in the same way as in [42, 41, 43, 44, 45] we have only to replace the parameters as follows

$$y \equiv \text{diag}(y_1, y_2) \rightarrow \frac{y}{1 + 2\pi B}. \quad (3.21)$$

This explains the extra factor $\sqrt{\det(1 + 2\pi\alpha'B)}$ of the $Dp - \overline{Dp}$ tension in the presence of the B -field.

4 RR Couplings and Superconnection

In this section we compute the RR couplings on non-BPS Dp -branes and brane-antibrane systems ($Dp - \overline{Dp}$) in a flat space within the framework of BSFT. Since the backgrounds of the closed string should be on-shell in BSFT, we can only consider RR-fields $C_{\mu_1 \dots \mu_p}$ which obey the equation of motion. This is sufficient to determine the RR couplings of D-branes.

Some of the RR couplings from the considerations of the descent relations [4, 1] and from the calculations of on-shell scattering amplitudes were already obtained in the literature [46] for non-BPS D-branes and [29] for brane-antibrane systems. However our off-shell calculations in BSFT give a more powerful and unified viewpoint as we will see. For example our method determines all the unknown coefficients of the higher order terms with respect to dT for non-BPS D-branes. Furthermore the resulting expressions in both systems can be identified with an intriguing mathematical structure known as superconnection [27]. This fact was already conjectured in [28, 29] for brane-antibrane systems. Here we find the explicit proof of this in BSFT and we point out that this structure can also be found in the RR couplings on non-BPS D-branes. These results give another evidence of the K-theory classification of D-brane charges [30, 28, 31].

In the first two subsections we assume $p = 9$. In the last subsection we determine the RR couplings for any p including the effects of non-abelian transverse scalars. As a result we obtain the complete forms of Myers terms [32] for both non-BPS D-branes and brane-antibrane systems.

4.1 RR Couplings on Non-BPS D-branes and Brane-Antibrane System in BCFT

We regard the small shifts of the RR backgrounds as the perturbations. These shifts are realized in BSFT as the insertions of the RR vertex operators in the disk Σ . The picture [47] of the vertex operators⁸ should be $(-\frac{1}{2}, -\frac{3}{2})$. This is because here we consider only one insertion of them and because the total picture number on the disk should be -2 . We mainly follow the conventions in [49], where the scattering amplitudes of closed string from D-branes were computed. The RR vertex operators are given by

$$V^{(-\frac{1}{2}, -\frac{3}{2})} = e^{-\frac{1}{2}\phi - \frac{3}{2}\tilde{\phi}} (P_- \hat{C})^{AB} S_A \tilde{S}_B, \quad (4.1)$$

$$\hat{C}^{AB} = \frac{1}{p!} (\Gamma^{\mu_1 \cdots \mu_p})^{AB} C_{\mu_1 \cdots \mu_p}, \quad (4.2)$$

where $\phi, \tilde{\phi}$ denote the bosonized superconformal ghost of left-moving and right-moving sector, respectively; we define S_A, \tilde{S}_B as the spin-fields of world-sheet fermions and P_- denotes the projection of the chirality. For more details of the notation for spinors see the appendix.

In the definition $S = Z$ of BSFT on non-BPS D-branes and brane-antibrane systems the ghost sectors are neglected in the same way as in the case of the BPS D-branes discussed in [35, 34]. Therefore it is difficult to handle the ghost parts of the above RR vertex operators explicitly. However it is natural to consider that the ghost parts and the matter parts are decoupled and that the ghost parts give the trivial contribution in

⁸For some subtleties, we recommend the readers to refer to [48].

the present calculations on the disk. Thus we can compute RR couplings taking only the matter parts into consideration.

Next we discuss the supersymmetry in the boundary interactions. The supersymmetry is completely preserved in the one dimensional boundary theory since all fermions at the boundary of the disk obey periodic boundary conditions due to the cut generated by the RR vertex. Therefore one can believe that the contributions from fermions and bosons are canceled with each other for nonzero-modes and that the boundary theory becomes topological in the sense of [50]. Note that in this paper we consider only D-branes in a flat space and we have no corrections from world-sheet instantons.

First we turn to non-BPS D9-branes and determine the RR couplings up to the overall normalization. To see the bose-fermi cancellation explicitly let us assume that the tachyon field $T(X)$ is a linear function as $T(X) = T_0 + u_\mu X^\mu$ and the field strength $F_{\mu\nu}$ is constant. Then the boundary interactions (2.8) are described as a free theory. Furthermore in the R-sector the zero-modes and nonzero-modes are completely decoupled and it is easy to see the bose-fermi cancellation for nonzero-modes because of the supersymmetry as follows

$$\frac{\partial}{\partial(u_\mu)^2} \log Z = -\frac{1}{8\pi} \int_0^{2\pi} d\tau < \xi^\mu(\tau) \xi^\mu(\tau) - 4\psi^\mu(\tau) \frac{1}{\partial_\tau} \psi^\mu(\tau) > = 0. \quad (\mu : \text{no sum}) \quad (4.3)$$

Note that this property in the R-sector is in strikingly contrast with the results (3.6) in the NS-sector.

Thus we have only to discuss the bosonic and fermionic zero-modes. The path integral of the former is written as an integral over the world-volume coordinates x^0, \dots, x^9 . The latters are divided into that of the world-sheet fermions ψ^μ and of the boundary fermion η . The integral of the zero modes of ψ^μ in the action (2.8) can be replaced with the trace over Γ -matrices in Hamiltonian formalism as follows:

$$\psi^\mu \rightarrow \frac{1}{\sqrt{2}} i^{\frac{1}{2}} \Gamma^\mu, \quad (4.4)$$

where the factor $i^{\frac{1}{2}}$ is due to the conformal map from the open string picture to the closed string picture⁹. Furthermore, we can compute the contribution from the boundary fermion in Hamiltonian formalism and its quantization is given by $\hat{\eta}^2 = \frac{1}{4}$. Notice that we should assume Γ^μ and $\hat{\eta}$ do anti-commute because in eq.(4.4) we have not included a cocycle factor. Then the result is given as follows including the RR vertex operator :

$$S = \tilde{\mu} \text{Tr} \int d^{10}x [: \exp[-\frac{1}{4}T^2 - 2i^{\frac{3}{2}}\sqrt{\pi}\Gamma^\mu \hat{\eta} \partial_\mu T + 2\pi F_{\mu\nu} \Gamma^\mu \Gamma^\nu] : (P_- \hat{C}) \hat{\eta}], \quad (4.5)$$

where $\tilde{\mu}$ represents the overall normalization and Tr denotes a trace with respect to both the Γ -matrices and the boundary fermion $\hat{\eta}$; the symbol $: :$ means that Γ -matrices

⁹See for example [51].

are antisymmetrized because any operators should be normal-ordered in Hamiltonian formalisms. Note that an extra zero mode of η is inserted due to its periodic boundary condition.

After we take the trace using the famous relation (A.11) between the Clifford algebra (A.10) and the differential forms (A.9) and recover $\alpha' = 2$, we easily obtain the final expression of the RR coupling on a non-BPS D9-brane¹⁰ as we will show in the appendix. Its non-abelian generalization is also straightforward using the expression (2.9) and one has only to add the trace of the Chan-Paton factor in front of the above expression. Thus the result is given up to the overall factor μ'^{11} by:

$$\begin{aligned} S &= \mu' \text{Tr}_\sigma \left[\int C \wedge \exp \left[-\frac{1}{4}T^2 - \sqrt{\frac{\pi\alpha'}{2}} i^{\frac{3}{2}} DT \sigma_1 + 2\pi\alpha' F \right] \sigma_1 \right], \\ &= i\mu' \text{Tr} \int C \wedge \exp \left[-\frac{1}{4}T^2 - \sqrt{\frac{\pi\alpha'}{2}} i^{\frac{1}{2}} DT + 2\pi\alpha' F \right] |_{\text{odd}}, \end{aligned} \quad (4.6)$$

where the Pauli matrix σ_1 is equivalent to the boundary fermion as $\sigma_1 \simeq 2\hat{\eta}$ and the trace Tr_σ in the first equation also involves this freedom; the covariant derivative of the Hermitian tachyon field on the non-BPS D-branes is denoted by $DT = dT - i[A, T]$. Also note that in the second expression only the terms which include the odd powers of DT should be remained because of the trace with respect to the boundary fermion and therefore we have represented this prescription by $|_{\text{odd}}$. From the above arguments, we can see that the boundary fermion η plays a crucial role in the computations of the RR couplings.

Next let us discuss the RR couplings of a D9 – $\overline{\text{D9}}$ in BSFT. In this case decoupling of the zero-modes and nonzero-modes should also occur. Even though it is not so easy to give the explicit proof of the bose-fermi cancellation in this case, it is natural to assume this cancellation. The path integral of the boundary fermions $\eta, \bar{\eta}$ can be represented by the RR-sector analog of the important formula (2.22):

$$\begin{aligned} \int D\eta D\bar{\eta} e^{-I_B} &= \text{Tr} \text{P} (-1)^F \exp \int_{-\pi}^{\pi} d\tau \mathbf{M}(\tau), \\ \mathbf{M}(\tau) &= \begin{pmatrix} i\dot{X}^\mu A_\mu^{(1)} - 2i\psi^\mu \psi^\nu F_{\mu\nu}^{(1)} - \frac{1}{2\pi} T\bar{T} & i\sqrt{\frac{2}{\pi}} \psi^\mu D_\mu T \\ -i\sqrt{\frac{2}{\pi}} \psi^\mu \bar{D}_\mu \bar{T} & i\dot{X}^\mu A_\mu^{(2)} - 2i\psi^\mu \psi^\nu F_{\mu\nu}^{(2)} - \frac{1}{2\pi} \bar{T}T \end{pmatrix}, \end{aligned} \quad (4.7)$$

where the insertion of $(-1)^F (= [\bar{\eta}, \eta])$ is due to the periodic boundary condition of $\eta, \bar{\eta}$ and can be replaced with the Pauli matrix σ_3 . Since we have only to take the zero modes into account, we can regard the path-ordered trace $\text{Tr} \text{P}$ as the ordinary trace and thus

¹⁰The leading term $\sim \int C \wedge e^{-\frac{1}{4}T^2} dT$ was already pointed out in [15].

¹¹Note that the above action is real if and only if μ' is proportional to $i^{-\frac{3}{2}}$. Later we will determine this as $\mu' = -i^{-\frac{3}{2}} T_9 / \sqrt{2}$.

we obtain

$$\int D\eta D\bar{\eta} DX D\psi e^{-I_0 - I_B} = \text{Str} \exp \begin{pmatrix} 2\pi F_{\mu\nu}^{(1)} \Gamma^\mu \Gamma^\nu - T\bar{T} & 2(i)^{\frac{3}{2}} \sqrt{\pi} \Gamma^\mu D_\mu T \\ -2(i)^{\frac{3}{2}} \sqrt{\pi} \Gamma^\mu \overline{D}_\mu T & 2\pi F_{\mu\nu}^{(2)} \Gamma^\mu \Gamma^\nu - \bar{T}T \end{pmatrix}, \quad (4.8)$$

where a supertrace Str is defined to be a trace with the insertion of σ_3 .

After we insert the RR vertex and again replace products of Γ -matrices with differential forms, we obtain the following RR couplings on a D9 – $\overline{\text{D9}}$:

$$S = \mu'' \text{Str} \int C \wedge \exp \begin{pmatrix} 2\pi\alpha' F^{(1)} - T\bar{T} & (i)^{\frac{3}{2}} \sqrt{2\pi\alpha'} DT \\ -(i)^{\frac{3}{2}} \sqrt{2\pi\alpha'} \overline{DT} & 2\pi\alpha' F^{(2)} - \bar{T}T \end{pmatrix}, \quad (4.9)$$

where μ'' is a real constant¹². This result coincides with the proposal in [29] as we will see in the next subsection.

The non-abelian generalization is also straightforward if the above abelian supertrace is replaced with the non-abelian one:

$$\text{Str} \text{diag}(a_1, a_2, \dots, a_N, b_1, b_2, \dots, b_M) = \sum_{i=1}^N a_i - \sum_{j=1}^M b_j, \quad (4.10)$$

where we assume that there are N D9-branes and M antiD9-branes. This result coincides with the proposal in [29] including the numerical factors as we will see in the next subsection.

In this way we have derived the explicit RR couplings on a non-BPS D9-brane and a D9 – $\overline{\text{D9}}$ system in BSFT. The point is that one can read off the RR couplings if one extracts the fermionic zero modes from the boundary action I_B . This may be said as a boundary topological model which can naturally lead to the notion of superconnection as we will see in the next subsection. Note also that the above results can be applied for general p -brane if the transverse scalars are set to zero.

4.2 Superconnection and K-theory Charge

Here we discuss the interpretation of the RR couplings on non-BPS D-branes and brane-antibrane systems in BSFT as superconnections [27]. For brane-antibrane systems this fact was first suggested in [28]. A definite relation between the RR couplings and the Chern character of the superconnection was proposed in the paper [29]. Our calculations in the previous subsection show that this interpretation indeed holds within the framework of BSFT as we will see below. Moreover we argue that such an interpretation can be applied to non-BPS D-branes and our previous calculations give an evidence for this.

¹²Even though one may think the factor $i^{\frac{3}{2}}$ strange at first sight, it is an easy task to show that the action is indeed real by expanding the exponential. Later we will determine this as $\mu'' = T_9$

Let us first review the definition and properties of superconnection following [27]. There are two kinds of superconnections: one is for even-cohomology and the other is for odd-cohomology. In the K-theoretic language the former is related to $K^0(M)$ and the latter to $K^1(M)$, where M is a manifold regarded as the D-brane world-volume. Both are defined as follows¹³:

Superconnection for $K^0(M)$

In this case we consider the \mathbf{Z}_2 -graded vector bundle $E = E^{(0)} \oplus E^{(1)}$, which can be directly applied to a brane-antibrane system if one identifies $E^{(0)}$ and $E^{(1)}$ as the vector bundle on the branes and antibranes, respectively. Then the endomorphism of this superbundle $X \in \text{End } E$ has the following \mathbf{Z}_2 -grading:

$$\deg(X) = \begin{cases} 0 & \text{if } X : E^{(0)} \rightarrow E^{(0)} \text{ or } E^{(1)} \rightarrow E^{(1)}, \\ 1 & \text{if } X : E^{(0)} \rightarrow E^{(1)} \text{ or } E^{(1)} \rightarrow E^{(0)}. \end{cases} \quad (4.11)$$

In addition, there is also a natural \mathbf{Z} -grading p if one considers the algebra of the differential forms $\Omega(M) = \oplus \Omega^p(M)$, where $\Omega^p(M)$ denotes the algebra of p -forms on M . The crucial observation is to mix these two gradings and to define the \mathbf{Z}_2 -grading for $\alpha \in \Omega^p(M, \text{End } E) = \Omega^p(M) \otimes \Omega^0(M, \text{End } E)$ as follows:

$$\alpha = \omega \otimes X \in \Omega^p(M) \otimes \Omega^0(M, \text{End } E), \quad \deg(\alpha) \equiv p + \deg(X), \quad (4.12)$$

where $\Omega^0(M, \text{End } E)$ denotes the space of sections of $\text{End } E$. Then the superalgebra is defined by the following rule:

$$(\omega \otimes X)(\eta \otimes Y) = (-1)^{\deg(X) \cdot \deg(\eta)} (\omega \eta \otimes XY), \quad (4.13)$$

and the supercommutator can be defined as:

$$[\alpha, \beta] = \alpha\beta - (-1)^{\deg(\alpha) \cdot \deg(\beta)} \beta\alpha. \quad (4.14)$$

An element of $\Omega^p(M, \text{End } E)$ can be written as a 2×2 matrix, where the diagonal elements and off-diagonal elements have even and odd degree of $\Omega^0(M, \text{End } E)$, respectively. We also define the supertrace as

$$\alpha \in \Omega(M, \text{End } E) = \begin{pmatrix} \alpha_1 & \alpha_2 \\ \alpha_3 & \alpha_4 \end{pmatrix}, \quad \text{Str}(\alpha) = \text{Tr}(\alpha_1) - \text{Tr}(\alpha_4) \in \Omega(M), \quad (4.15)$$

where Tr denotes the ordinary trace of vector bundles. Note that the supertrace vanishes on supercommutators.

¹³We include the explicit factor $\frac{i}{2\pi}$ in front of the field strength which was omitted for simplicity in the original paper [27]. This is the reason why the factor $i^{\frac{1}{2}}$ does appear in the expressions below.

Let us now define a superconnection on E to be an operator $\mathcal{D} = d + \mathcal{A}$ on $\Omega(M, E)$ of odd degree satisfying the derivation property:

$$\mathcal{D}(\omega\phi) = (d\omega)\phi + (-1)^{\deg(\omega)}\omega(\mathcal{D}\phi), \quad \omega \in \Omega(M), \quad \phi \in \Omega(M, E). \quad (4.16)$$

For local calculations familiar for physicists one can regard \mathcal{A} as a degree odd element of $\Omega(M, \text{End } E)$:

$$\mathcal{D} = d + \mathcal{A} = \begin{pmatrix} d + A^{(1)} & \sqrt{2\pi i}T \\ \sqrt{2\pi i}\bar{T} & d + A^{(2)} \end{pmatrix}, \quad (4.17)$$

where the factor $\sqrt{2\pi i}$ has been included for later convenience. The diagonal parts $d + A^{(1)}, d + A^{(2)}$ denote the ordinary gauge connections of vector bundles $E^{(1)}, E^{(2)}$, respectively. T denotes a odd degree endomorphism of E . Notice that in this definition the exterior derivative d does *anti-commute* with any odd element in $\text{End } E$.

Then the curvature \mathcal{F} of a superconnection \mathcal{D} is defined to be an even degree element of $\Omega(M, \text{End } E)$:

$$\begin{aligned} \mathcal{F} &= \mathcal{D}^2 = d\mathcal{A} + \mathcal{A}^2 \\ &= \begin{pmatrix} F^{(1)} + 2\pi i T\bar{T} & \sqrt{2\pi i}DT \\ \sqrt{2\pi i}D\bar{T} & F^{(2)} + 2\pi i\bar{T}T \end{pmatrix}, \end{aligned} \quad (4.18)$$

where we have defined $DT = dT + A^{(1)}T + TA^{(2)}$ ¹⁴.

The ‘‘Chern character’’ of this superconnection is given by

$$\text{Str exp}\left(\frac{i}{2\pi}\mathcal{D}^2\right) = \text{Str exp}\frac{i}{2\pi}\mathcal{F}. \quad (4.19)$$

It is easy to see that this is closed because

$$d(\text{Str}\mathcal{D}^{2n}) = \text{Str}[\mathcal{D}, \mathcal{D}^{2n}] = 0. \quad (4.20)$$

Furthermore as shown in the main theorem in [27], its cohomology class does not depend on the choice of T . In other words, this Chern character defines the same element of $K^0(M)$ irrespective of T :

$$\text{Str exp}\left(\frac{i}{2\pi}\mathcal{D}^2\right) \simeq \text{ch}(E_1) - \text{ch}(E_2) \in H^{\text{even}}(M, \mathbf{Q}) \cong K^0(M), \quad (4.21)$$

where $\text{ch}(E)$ denotes the ordinary Chern character and we have applied the Chern isomorphism, which states that the even cohomology and the K-group $K^0(M)$ are equivalent if \mathbf{Q} is tensored.

¹⁴Note that since T is an odd element, it anti-commutes with any one form. Therefore we can say that T does couple to the relative gauge field $A^{(1)} - A^{(2)}$.

Superconnection for $K^1(M)$

The first step to define the second superconnection is to regard a bundle E as a module over the Clifford algebra $C_1 = \mathbf{C} \oplus \mathbf{C}\sigma_1$. In other words, we define the endomorphism of this superbundle as $\text{End}_\sigma E = \text{End } E \otimes C_1$. Let us call all elements which include σ_1 degree odd and the others degree even. In the physical context these correspond to the fields on non-BPS D-branes which belong to GSO odd and even sectors, respectively. The supertrace on $\text{End}_\sigma E$ is defined as follows:

$$\text{Tr}_\sigma(X + Y\sigma_1) = 2\text{Tr}(Y), \quad (4.22)$$

where $X, Y \in \text{End}_\sigma E$ are degree even elements. Further we mix the degree of differential forms in the same way as in the previous case eq.(4.12),(4.13) and (4.14).

A superconnection on E is defined locally to be an odd element as follows

$$\mathcal{D} = d + \mathcal{A} = d + A - \sqrt{\frac{i\pi}{2}}T\sigma_1, \quad (4.23)$$

where A is an ordinary connection and T is a self-adjoint endomorphism. The curvature of this is also defined as

$$\begin{aligned} \mathcal{F} &= \mathcal{D}^2 = d\mathcal{A} + \mathcal{A}^2 \\ &= F - \sqrt{\frac{i\pi}{2}}DT\sigma_1 - \frac{i\pi}{2}T^2, \end{aligned} \quad (4.24)$$

where we have defined $DT = dT - i[A, T]$. Then the “odd Chern character” is given by

$$\text{Tr}_\sigma \exp\left(\frac{i}{2\pi}\mathcal{D}^2\right) = \text{Tr}_\sigma \exp \frac{i}{2\pi}\mathcal{F}. \quad (4.25)$$

The main theorem in [27] again tells us that this character is closed and its cohomology class does not depend on the choice of T . Further we can regard this as an element of K-theory group $K^1(M)$:

$$\text{Tr}_\sigma \exp\left(\frac{i}{2\pi}\mathcal{D}^2\right) \in H^{odd}(M, \mathbf{Q}) \cong K^1(M). \quad (4.26)$$

Physical interpretations

It is a well-known fact that the RR couplings on a BPS D9-brane are written by using Chern characters [52, 53, 54]

$$S = T_9 \text{Tr} \int_M C \wedge \exp 2\pi\alpha' F, \quad (4.27)$$

where we have assumed that the world-volume (=spacetime) M is flat. As can be deduced from this [30], the D-brane charges in type IIB were proposed to be regarded as an element of K-theory group $K^0(M)$, which is equivalent to the Chern character up to torsion via the Chern isomorphism. This proposal was strongly convinced in the study of tachyon condensation on brane-antibrane systems [28]. The original definition of $K^0(M)$ is given by considering the equivalence class of a pair of vector bundles (E_1, E_2) . This definition can be naturally seen as a mathematical description of brane-antibrane systems. Moreover it was pointed out that the other K-theory group $K^1(M)$ is related to the tachyon condensation on non-BPS D9-branes [31]. This leads to the classification of the D-brane charges in type IIA. At first sight, there are two different physical observations about the generation of K-theory charges: the K-theory charges from RR couplings on a BPS D-brane and those from the tachyon condensation. Then it is natural to ask if we can directly fill this gap in string field theories. The answer to this question is yes in BSFT and the key is superconnections as we see below.

The role of superconnections in the D-brane physics is explicit if one notes that the RR couplings on D9- $\overline{\text{D9}}$ systems and non-BPS D9-branes can be expressed as wedge products of RR-fields and the Chern characters of superconnections:

$$S = \mu'' \text{Str} \int_M C \wedge \exp\left(\frac{i}{2\pi} \mathcal{F}\right) \quad (\text{for a D9-}\overline{\text{D9}}), \quad (4.28)$$

$$S = \mu' \text{Tr}_\sigma \int_M C \wedge \exp\left(\frac{i}{2\pi} \mathcal{F}\right) \quad (\text{for a non-BPS D9-brane}), \quad (4.29)$$

where the curvature \mathcal{F} in the first equation represents the superconnection for $K^0(M)$ and in the second for $K^1(M)$. One of the expression (4.28) was already proposed in [29]. One can indeed transform these mathematical expressions eq.(4.18),(4.24) into the physical ones eq.(4.9),(4.6) by following the prescription¹⁵:

$$D = d + A \rightarrow 2\pi\sqrt{\alpha'} D = 2\pi\sqrt{\alpha'}(d - iA). \quad (4.30)$$

Note that if one assumes the descent relation [4, 1], one can formally obtain the coupling (4.29) from (4.28). Here the descent relation argues that one can reduce the degree of freedom on a brane-antibrane to that on a non-BPS D-brane if one projects the Chan-Paton factor Λ on a brane-antibrane by the following action:

$$(-1)^{F_L} : \Lambda \rightarrow \sigma_1 \Lambda \sigma_1, \quad (4.31)$$

¹⁵Also note that for a brane-antibrane we need an additional minus sign in front of \overline{DT} . This occurs due to the following reason. The mathematical definition of the superconnection for $K^0(M)$ assumes that an odd form anti-commutes with an odd degree endomorphism as in eq.(4.13). On the other hand, in the physical expression eq.(4.9) it does commute.

where F_L denotes the spacetime fermion number in the left-moving sector. Thus we have proved that the proposal in [29] is correct if we consider brane-antibranes in BSFT. Also the second new expression (4.29) is interesting because this explicitly shows that we can obtain the odd forms which correspond to $K^1(M)$ by including the Hermitian tachyon field.

Then let us turn to the first question. In the expression (4.28) we can smoothly connect the following two regions through the process of a tachyon condensation. Before the condensation the RR charge in (4.28) comes only from the gauge field-strengths. On the other hand when the tachyon maximally condenses, the contribution from the tachyon field dominates. For a trivial example, in [27] it was shown that if the tachyon field T is invertible at some regions in M then the Chern character (4.19) does locally vanish there. Physically this is natural since the condensation of a constant tachyon leads to the decay into the vacuum and the lower dimensional charges are generated only at the regions where T is not invertible. The same theorem also holds for the odd case (4.25).

A nontrivial example of the tachyon field which is not invertible is given by the Atiyah-Bott-Shapiro construction (3.19). The important point is that RR charges or equally K-theory charges do not change globally during the tachyon condensation as is shown in eq.(4.21) and thus the charges are quantized in off-shell regions. To give a more concrete picture, let us remind the calculation of the tachyon condensation in the previous section. If one calculates the RR coupling (4.28) for the vortex-type tachyon configuration (3.1) and integrates it over the world-volume, then it is easy to see that the RR charges are independent of the parameters u_1, u_2 except the “singular points” $u_1 = 0$ or $u_2 = 0$. This analysis of the tachyon condensation determines the values of μ' and μ'' as $\mu' = -i^{-\frac{3}{2}} \frac{T_9}{\sqrt{2}}$ and $\mu'' = T_9$. Notice that the topology of the tachyon field T becomes trivial at the points $u_1 = 0$ or $u_2 = 0$ and therefore one can not regard T as an element in the desirable endomorphism. In this way we can relate D-brane charges in the RR-couplings to D-brane charges due to tachyon condensations directly in BSFT.

4.3 RR Couplings of Transverse Scalars: Myers Terms

As we have seen above, the BSFT calculations determine the RR couplings on the various systems of 9-branes exactly. If one wants to obtain the RR couplings for a single $p(\neq 9)$ -brane, one has only to interpret the RR-fields as their pull-backs (see eq.(4.36)) to the D-brane world-volume.

However their non-abelian generalizations (4.27),(4.28) and (4.29) are incomplete for $p(\neq 9)$ -branes from the viewpoint of T-duality. As pointed out in [32] for BPS Dp-branes, in order to recover the T-duality symmetry we must take the transverse scalars Φ^i ($i = p+1, \dots, 9$) into account. For example if a pair of scalars is noncommutative $[\Phi^i, \Phi^j] \neq 0$, then D($p+2$)-brane charges emerge and therefore we should include this

effect. Those terms which represent such an effect are called Myers terms and their structures were investigated in [32, 55, 56, 57, 58]. Here we argue that if one would like to determine all of the Myers terms for any D-branes, then one has only to compute RR couplings in BSFT including the transverse scalars. Here we set the value of B-field to zero.

First let us determine the Myers terms for non-BPS D-branes. We use the non-abelian boundary action (2.9) with an additional term due to the transverse scalars

$$-i \int_{\partial\Sigma} d\tau d\theta \bar{\Delta} \Phi_i(\mathbf{X}) D_n \mathbf{X}^i \Delta, \quad (4.32)$$

where we have defined the T-dualized covariant derivative as $D_n = \partial/\partial\theta + i\theta\partial/\partial\sigma$; σ is the world-sheet coordinate transverse to the boundary $\partial\Sigma$. Note that if one wants to discuss BPS D-branes, one has only to set $T = 0$, $\Gamma = 0$ in eq.(2.9). After we integrate out the auxiliary fields and extract the zero modes as was done in (4.5), we obtain the additional terms:

$$: \exp[\cdots + 2i^{\frac{1}{2}}\sqrt{\pi}[\Phi_i, T]\Gamma^i\hat{\eta} - 2i\pi[\Phi_i, \Phi_j]\Gamma^i\Gamma^j - 4\pi D_\mu\Phi_i\Gamma^\mu\Gamma^i] : , \quad (4.33)$$

where \cdots denotes the contribution from (4.5). When one estimates the trace of Γ -matrices and is reminded of the calculations in the appendix, note that the matrices Γ^i ($i = p+1, \dots, 9$) contract the indices of RR-fields C_{μ_1, \dots, μ_q} in contrast with the matrices Γ^μ ($\mu = 0, \dots, p$). Then we obtain the following additional RR couplings (Myers terms) to eq.(4.6):

$$S = \mu' \text{Tr} \int [\exp[\cdots + \sqrt{\frac{\pi\alpha'}{2}} i^{\frac{1}{2}}[\mathbf{i}_\Phi, T]\sigma_1 - 2\pi\alpha' i \mathbf{i}_\Phi \mathbf{i}_\Phi - 2\pi\alpha' \mathbf{i}_{D\Phi}] \sigma_1 \wedge C], \quad (4.34)$$

where Tr denotes both the trace with respect to Chan-Paton factors and the trace defined by eq.(4.22); \mathbf{i}_Φ and $\mathbf{i}_{D\Phi}$ denote the interior product by Φ and $D\Phi$:

$$\begin{aligned} A &= \frac{1}{r!} A_{\nu_1, \nu_2, \dots, \nu_r} dx^{\nu_1} dx^{\nu_2} \cdots dx^{\nu_r}, \\ \rightarrow \mathbf{i}_\Phi A &= \frac{1}{(r-1)!} \Phi^i A_{i, \nu_2, \dots, \nu_r} dx^{\nu_2} \cdots dx^{\nu_r}, \quad \mathbf{i}_{D\Phi} A = \frac{1}{(r-1)!} D_\mu \Phi^i A_{i, \nu_2, \dots, \nu_r} dx^\mu dx^{\nu_2} \cdots dx^{\nu_r}. \end{aligned} \quad (4.35)$$

In the above RR coupling the first term is peculiar to non-BPS D-branes. The second corresponds to the generation of higher dimensional D-brane charges due to the noncommutative transverse scalars. The last term changes the RR fields C into their covariantized expression $\tilde{P}[C]$ of the pull-backs $P[C]$:

$$P[C]_{\mu_1, \dots, \mu_q} = C_{\nu_1, \dots, \nu_p} \left(\frac{\partial y^{\nu_1}}{\partial x^{\mu_1}} \right) \cdots \left(\frac{\partial y^{\nu_q}}{\partial x^{\mu_q}} \right), \quad (4.36)$$

where $y^\mu = x^\mu$ ($\mu = 0, \dots, p$) denote the coordinates of the p-brane world-volume and we also define $y^i = -2\pi\alpha'\Phi^i$ ($i = p+1, \dots, 9$). In addition “covariantized” means that all derivatives $\partial_\mu\Phi^i$ in the above definition (4.36) should be replaced with covariant derivatives $D_\mu\Phi^i$. Then the total RR-couplings are given by

$$S = i\mu' \text{Tr} \left[\int \tilde{P} \left[e^{-2\pi\alpha' i \mathbf{i}_\Phi \mathbf{i}_\Phi + \sqrt{\frac{\pi\alpha'}{2i}} [\mathbf{i}_\Phi, T]} \wedge C \right] \wedge e^{-\frac{1}{4}T^2 - \sqrt{\frac{\pi\alpha' i}{2}} DT + 2\pi\alpha' F} \right] |_{\text{odd}}, \quad (4.37)$$

where the trace Tr is a symmetric trace with respect to $[\Phi^i, \Phi^j]$, $[\Phi^i, T]$, T^2 , DT , F and $D\Phi^i$. For example the term proportional to $[\mathbf{i}_\Phi, T]$ was already pointed out in [56]. On the other hand if we set T to zero and neglect the restriction to odd forms, then one gets the RR couplings for BPS Dp-branes, matching with the results in [32]. In this way we have determined the complete form of Myers terms for non-BPS D-branes in BSFT and these include new terms which are higher powers of $[\mathbf{i}_\Phi, T]$. Note also that our calculations explicitly preserve the T-duality symmetry $A_\mu \leftrightarrow -\Phi_i$.

Then let us turn to the final task in this section: Myers terms in brane-antibrane systems. In the same way as before we have only to add the extra terms which involve transverse scalars. As a result the matrix in the exponential of eq.(4.9) includes Myers terms as follows:

$$\begin{pmatrix} 2\pi\alpha'(F^{(1)} - i\mathbf{i}_{\Phi^{(1)}}\mathbf{i}_{\Phi^{(1)}} - \mathbf{i}_{D\Phi^{(1)}}) - T\bar{T} & (i)^{\frac{3}{2}}\sqrt{2\pi\alpha'}\{DT + i(\mathbf{i}_{\Phi^{(1)}T} - \mathbf{i}_{T\Phi^{(2)}})\} \\ -(i)^{\frac{3}{2}}\sqrt{2\pi\alpha'}\{\bar{D}\bar{T} - i(\mathbf{i}_{\bar{T}\Phi^{(1)}} - \mathbf{i}_{\Phi^{(2)}\bar{T}})\} & 2\pi\alpha'(F^{(2)} - i\mathbf{i}_{\Phi^{(2)}}\mathbf{i}_{\Phi^{(2)}} - \mathbf{i}_{D\Phi^{(2)}}) - \bar{T}T \end{pmatrix}, \quad (4.38)$$

where we interpreted Str in eq.(4.9) as both the symmetric trace with respect to Chan-Paton factors and the original supertrace. Note that if one requires that the branes and the antibranes always have the common world-volume, then we get $\Phi^{(1)} = \Phi^{(2)} (= \Phi)$. In this case we can find intriguing terms in the RR couplings:

$$S \sim \int_{\text{p-brane}} C_{i,j,\dots}^{(p+3)} \text{Tr}[\Phi^i, T][\Phi^j, \bar{T}] e^{-T\bar{T}}. \quad (4.39)$$

5 The World-Volume Action for Brane-Antibrane System

In this section we compute the BSFT action for tachyons and gauge fields in the brane-antibrane system perturbatively.

First, we will show below that the action computed from (2.18) can be written as

$$\begin{aligned} Z = T_9 \int d^{10}x e^{-T\bar{T}(x)} & \left[\sqrt{-\det\{g_{\mu\nu} + 4\pi F_{\mu\nu}^{(1)}(x)\}} + \sqrt{-\det\{g_{\mu\nu} + 4\pi F_{\mu\nu}^{(2)}(x)\}} \right. \\ & \left. + \sum_{n=1}^{\infty} \mathcal{G}_{2n}(F_{\mu\nu}^{(i)}, T, \bar{T}, D_\rho) \right], \quad (5.1) \end{aligned}$$

where \mathcal{G}_{2n} is a $2n$ -derivative term constructed from $F_{\mu\nu}^{(i)}, T, \bar{T}$ and $2n$ covariant derivatives D_μ . Note that, for example, $F_{\mu\nu}^{(-)}T$ is regarded as a 2-derivative term and should be included in \mathcal{G}_2 because of the identity $[D_\mu, D_\nu]T = -iF_{\mu\nu}^{(-)}T$. These ambiguities are reminiscent of the case of the non-Abelian Born-Infeld action [59] in which $[F_{\mu\nu}, F_{\gamma\sigma}] = i[D_\mu, D_\nu]F_{\gamma\sigma}$ was regarded as a derivative term.

What does this action represent? We first answer the question. As shown in [40], this action (5.1) is regarded as an on-shell effective action for T and A_μ , in which the massive modes are integrated out, or an off-shell BSFT action with other modes than T and A_μ setting to zero. However, if the one-point function of the massive fields vanishes in all the off-shell region, then we can regard this action as the off-shell BSFT action, in which the massive fields are integrated out.

The explanation is as follows. First we expand the full string field action by the power series of the massive fields (λ^i):

$$S[T, A_\mu, \lambda^i] = S^{(0)}[T, A_\mu] + \lambda^i S_i^{(1)}[T, A_\mu] + \lambda^i \lambda^j S_{ij}^{(2)}[T, A_\mu] + \cdots \quad (5.2)$$

If we want to obtain the effective string field action including only the tachyon and the gauge fields, then we integrate out the massive fields. Note that “integrate out” means that we only insert the solution of the equation of motion for λ^i because we want to obtain *the tree level* effective string field action. The general solution of the equation of motion for λ^i is very complicated. However, if $S_i^{(1)}[T, A_\mu]$ (the one-point function of λ^i) vanishes, then we can easily find one solution of the equation of motion, that is $\lambda^i = 0$. Therefore in this case we can regard the $S^{(0)}[T, A_\mu]$ as the effective action, in which the massive fields are integrated out. $S^{(0)}[T, A_\mu]$ is just the action we are able to calculate from the renormalizable sigma model action where the massive fields are set to zero. Therefore the crucial point to obtain the effective action is whether $S_i^{(1)}[T, A_\mu]$ does vanish or not. From the argument of [14, 15], $S_i^{(1)}[T, A_\mu]$ vanishes at least at the conformal fixed point of the renormalization group flow (on shell point), however in the off shell region it is non-trivial. In [14] they say that it is correct for the free sigma model action because from the relation of BSFT:

$$\frac{\partial S}{\partial \lambda^i} = \beta^j G_{ij}(\lambda), \quad (5.3)$$

(where $G_{ij}(\lambda)$ is some positive definite metric) $\frac{\partial S}{\partial \lambda^i}|_{\lambda=0}$ vanishes. However, in this argument, the only ambiguity is whether the non-diagonal elements of $G_{ij}(\lambda)$, where j corresponds to T, A_μ and i to the massive fields, does vanish or not (note that $\beta^i|_{\lambda=0} = 0$ (i : the massive fields) and $\beta^{T,A}|_{\lambda=0} \neq 0$). However, from the success and correctness of the tachyon condensation in [14, 15] we can consider that above facts hold in the case of the free sigma model action. Therefore if the above facts hold not only for the free sigma model but also for our renormalizable one (eq.(2.13)), $S^{(1)}[T, A_\mu]$ vanishes in off-shell re-

gions and we can regard eq.(5.1) as the effective action, in which the massive modes are integrated out. However, we can not assert that it is true.

Now we prove eq.(5.1). We use the matrix form of the world-sheet action

$$Z = \int DX D\psi \exp[-I_0(X, \psi)] \text{Tr P} \exp \int_{-\pi}^{\pi} d\tau \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix}, \quad (5.4)$$

where

$$\begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix} = \begin{bmatrix} i\dot{X}^\mu A_\mu^{(1)} - 2i\psi^\mu \psi^\nu F_{\mu\nu}^{(1)} - \frac{1}{2\pi} T\bar{T} & i\sqrt{\frac{2}{\pi}} \psi^\mu D_\mu T \\ -i\sqrt{\frac{2}{\pi}} \psi^\mu \overline{D_\mu T} & i\dot{X}^\mu A_\mu^{(2)} - 2i\psi^\mu \psi^\nu F_{\mu\nu}^{(2)} - \frac{1}{2\pi} \bar{T}T \end{bmatrix}. \quad (5.5)$$

Now we expand X^μ from zero mode x^μ as $X^\mu = x^\mu + \xi^\mu$ and path integrate ξ^μ and ψ^μ (ψ does not include the zero mode in this case.). Then from the expansion $T\bar{T}(X) = T\bar{T}(x) + \xi^\mu (\partial_\mu(T\bar{T}))(x) + \dots = T\bar{T}(x) + \xi^\mu (D_\mu(T\bar{T}))(x) + \dots$, we can replace $T\bar{T}(X)$ in Z by $T\bar{T}(x)$ if we remove the derivative terms which can be included in \mathcal{G}_{2n} . The $F_{\mu\nu}^{(i)}(X)$ terms can also be replaced by $F_{\mu\nu}^{(i)}(x)$. Furthermore we see that the contributions from the off diagonal part of the matrix M_{ab} have the form of \mathcal{G}_{2n} since they can be expanded as $D_\mu T(X) = D_\mu T(x) + \xi^\nu (\partial_\nu(D_\mu T))(x) + \dots$. The terms $i\dot{X}^\mu A_\mu^{(i)}(X)$ in the diagonal part are combined with the other non-gauge covariant terms to give gauge covariant ones. Therefore we conclude that the action for the brane-antibrane system becomes (5.1). Similarly, we can show that the action for a system of n branes and m anti-branes becomes

$$Z = T_9 \int d^{10}x \left(\text{SymTr} \left[e^{-T\bar{T}} \sqrt{-\det\{g_{\mu\nu} + 4\pi F_{\mu\nu}^{(1)}\}} + e^{-\bar{T}T} \sqrt{-\det\{g_{\mu\nu} + 4\pi F_{\mu\nu}^{(2)}\}} \right] + \sum_{n=1}^{\infty} \mathcal{G}_{2n}(F^{(i)}, T, \bar{T}, D_\mu) \right), \quad (5.6)$$

where SymTr denotes the symmetrized trace for $T\bar{T}$, $\bar{T}T$ and $F_{\mu\nu}^{(i)}$ [59].

Now we will use this action in order to investigate the non-commutative soliton in the brane-antibrane system [60, 61, 25]. Here we simply assume that $S_i^{(1)}[T, A_\mu]$ is zero or derivative terms, then the action (5.6) is exact even for the off shell fields. According to the argument in [62] if we include the background constant B -field, then the propagator is modified and the action can be written as the non-commutative field theory when we use the point splitting regularization for the world-sheet theory. This will be true at least for the on-shell fields. We assume here that this is also true for the off-shell action since the evidences for this have been obtained [44, 42, 41]. Then the non-commutative action for the brane-antibrane system with background constant B -field becomes the same form as (5.6) where the product is $*$ -product and closed string metric $g_{\mu\nu}$ and coupling g_s are replaced by open string metric $G_{\mu\nu}$ and G_s , respectively. We should also replace the

field strength $F_{\mu\nu}^{(i)}$ by $\hat{F}_{\mu\nu}^{(i)} + \Phi_{\mu\nu}$, where $\Phi_{\mu\nu}$ represents a freedom to relate closed string quantities to open string quantities. Below we take $\Phi_{\mu\nu} = -B_{\mu\nu}$ for simplicity [62, 25].

In [25] the exact non-commutative solitons for the string field theories were obtained using the technique called solution generating technique, which is also useful for the BPS case [63] [64]. For the brane-antibrane system, they assumed the form of action which does not vanishes at the closed string vacuum $T = T_0$. Our action (5.6), however, vanishes at the minimum $T = T_0 = \infty$ and does not have the form assumed in [25]. Thus we should confirm whether their construction of the exact soliton works for a noncommutative version of our brane-antibrane action (5.1) or not. In order to use the solution generating technique, we regard the fields on the non-commutative field theory as operators on Fock space. In [25] an almost gauge transformation was defined as

$$\begin{aligned} D_\mu^{(i)} &\rightarrow S^{(i)} D_\mu^{(i)} S^{(i)\dagger}, \\ T &\rightarrow S^{(1)} T S^{(2)\dagger}, \end{aligned} \quad (5.7)$$

where $D^{(i)}$ is a covariant derivative operator $D^{(i)} = d - iA^{(i)}$ and $i = 1, 2$. Here $S^{(i)}$ is an almost unitary operator which satisfies $S^{(i)\dagger} S^{(i)} = 1$ and $S^{(i)} S^{(i)\dagger} = 1 - P^{(i)}$ where $P^{(i)}$ is a projection operator. First, we start from the trivial vacuum $A_\mu^{(i)} = 0$ and $T = T_0 (= \infty)$, which is a solution of the equations of motion for the noncommutative version of the action (5.1). Then the configuration constructed by the above transformation becomes a nontrivial exact solution of the equations of motion from the argument in [25].

We can see that the tension of this soliton is correct value. The process of its calculation is almost same as in [25]. The only difference from [25] is the form of the action, especially the explicit form of terms of field strengths without covariant derivatives. These terms in our action are the sum of Born-Infeld actions multiplied by the function of the tachyon, $\exp(-\bar{T}T)$, or $\exp(-T\bar{T})$. We note that the tachyon $\bar{T}T, T\bar{T}$ and the field strength $\hat{F}_{\mu\nu}^{(i)} + \Phi_{\mu\nu} \sim [D_\mu^{(i)}, D_\nu^{(i)}]$ are transformed to $|T_0|^2(1-P^{(2)})$, $|T_0|^2(1-P^{(1)})$ and $S^{(i)}[D_\mu^{(i)}, D_\nu^{(i)}]S^{(i)\dagger} \sim \Phi_{\mu\nu}(1-P^{(i)})$ respectively. Here we can obtain

$$V(\bar{T}T)[D_\mu^{(2)}, D_\nu^{(2)}] = 0, \quad (5.8)$$

for the soliton configuration from the equation $V(\bar{T}T) = V(\bar{T}T) - V(0) + V(0) = (V(\bar{T}_0 T_0) - V(0))(1 - P^{(2)}) + V(0) = V(0)P^{(2)}$ where $V(\bar{T}T) \sim \exp(-\bar{T}T)$ and $V(\bar{T}T) = 0$ at $T = T_0 = \infty$. Therefore for this soliton configuration constructed from the vacuum where the action vanishes, the sum of Born-Infeld actions remains to vanishes except the gauge fields independent term, i.e. the tachyon potential. Hence the soliton constructed in [25] is an exact solution of the brane-antibrane action which represents N_1 Dp-brane and N_2 anti Dp-brane, where $N_i = \dim(\text{Ker}(1 - P^{(i)}))$.

Note that the action evaluated at this soliton configuration has a non-zero value, while the action evaluated at the closed string vacuum $T = \infty$ vanishes. In [25] they argued

that the action can not vanish even at the closed string vacuum from an observation that the BPS brane after the tachyon condensation has non-zero mass. In fact, our action has nonzero value for the soliton solution and is consistent.

The properties of vanishing kinetic terms may be required from the observation that at the closed string vacuum in order to solve the $U(1)$ problem the strong coupling effects should be important and the vanishing kinetic terms almost mean the strong coupling physics [65, 20, 66, 67].

Next we compute the brane-antibrane effective action as a sigma model partition function perturbatively up to α'^2 . Hereafter we will restore the dimension-full parameter α' by including a factor $\alpha'/2$. Here we use the regularized correlation function

$$\langle \xi^\mu(\tau) \xi^\mu(\tau') \rangle = \alpha' \sum_{m \in \mathbf{Z} \neq 0} \frac{1}{|m|} e^{im(\tau - \tau') - \epsilon|m|} = 2\alpha' \sum_{m \in \mathbf{Z} > 0} \frac{1}{m} \cos(m(\tau - \tau')) e^{-\epsilon|m|}, \quad (5.9)$$

$$\langle \psi^\mu(\tau) \psi^\mu(\tau') \rangle = -\frac{i}{2} \sum_{r \in \mathbf{Z} + \frac{1}{2}} \frac{r}{|r|} e^{ir(\tau - \tau') - \epsilon|r|} = \sum_{m \in \mathbf{Z} + \frac{1}{2} > 0} \sin(r(\tau - \tau')) e^{-\epsilon|r|}. \quad (5.10)$$

This regularization keeps world-sheet supersymmetry and the spacetime gauge invariance which corresponds to world-sheet global symmetry [35, 34]. First we expand fields in (2.18) as

$$\begin{aligned} T\bar{T}(X) &= T\bar{T}(x) + \xi^\mu (D_\mu(T\bar{T}))(x) + \cdots + \frac{1}{4!} \xi^\sigma \xi^\rho \xi^\nu \xi^\mu (D_\sigma D_\rho D_\nu D_\mu(T\bar{T}))(x) \cdots, \\ A_\mu^{(i)}(X) &= A_\mu^{(i)}(x) + \xi^\nu \partial_\nu A_\mu^{(i)}(x) + \cdots, \quad F_{\mu\nu}^{(i)}(X) = F_{\mu\nu}^{(i)}(x) + \xi^\rho (D_\rho F_{\mu\nu}^{(i)})(x) + \cdots, \\ D_\mu T(X) &= D_\mu T(x) + \xi^\nu (\partial_\nu (D_\mu T))(x) + \frac{1}{2} \xi^\rho \xi^\nu (\partial_\rho \partial_\nu (D_\mu T))(x) \cdots. \end{aligned} \quad (5.11)$$

Then we can compute the partition function usually by the perturbation in α' . Since the actual computations are somewhat complicate, we will only show the outline of the computation and the result below.

The gauge invariance of the effective action can be checked by replacing the ∂_μ by D_μ and picking the terms which depend on $A_\mu^{(i)}$. For example, the coefficient of the term $A_\rho^{(-)}(\overline{D^\mu T})(\partial_\rho D_\mu T)$ is proportional to

$$\sum_{r, m > 0} \frac{1}{m} \left(\frac{1}{r+m} + \frac{1}{r-m} \right) e^{-(r+m)\epsilon} + \sum_{r, m > 0} \frac{1}{r} \left(\frac{1}{r+m} + \frac{1}{m-r} \right) e^{-(r+m)\epsilon} - \sum_{r, m > 0} \frac{2}{rm} e^{-(r+m)\epsilon}, \quad (5.12)$$

which is indeed zero, where $r \in \mathbf{Z} + \frac{1}{2} > 0$ and $m \in \mathbf{Z} > 0$. The other terms can be calculated explicitly by the formulae in [34] except a finite constant

$$\gamma_0 = \lim_{\epsilon \rightarrow 0} \left(\sum_{r, m > 0} \frac{1}{m} \left(\frac{1}{r+m} + \frac{1}{r-m} \right) e^{-(r+m)\epsilon} - (\log \epsilon)^2 \right). \quad (5.13)$$

The result up to α'^2 can be rearranged in a rather simple form:

$$\begin{aligned}
S = Z = T_9 e^{-\bar{T}_R T_R} & \left[2 + 8\alpha' \log 2 D_\mu T_R \overline{D_\mu T_R} + \alpha'^2 \pi^2 \left((F_{\mu\nu R}^{(1)})^2 + (F_{\mu\nu R}^{(2)})^2 \right) \right. \\
& + 4\alpha'^2 \gamma_0 D_\nu D_\mu T_R D_\nu D_\mu \overline{T_R} + 32\alpha'^2 i (\log 2)^2 F_{\mu\nu R}^{(-)} D_\mu T_R D_\nu \overline{T_R} \\
& + 2\alpha'^2 \left(8(\log 2)^2 - \frac{1}{3}\pi^2 \right) (D_\mu T_R D_\mu \overline{T_R})^2 - \alpha'^2 \frac{2}{3}\pi^2 (D_\mu T_R)^2 (D_\nu \overline{T_R})^2 \\
& + \frac{\pi^2}{6} \alpha'^2 \left((D_\mu D_\nu T_R) \overline{T_R} + T_R (D_\mu D_\nu \overline{T_R}) \right) \\
& \left. \times \left(D_\mu D_\nu (\overline{T_R} T_R) + D_\nu \overline{T_R} D_\mu T_R + D_\mu \overline{T_R} D_\nu T_R \right) \right], \tag{5.14}
\end{aligned}$$

where we renormalized the tachyon field only as

$$\begin{aligned}
T &= T_R + \alpha' \log \epsilon D_\mu D_\mu T_R + \frac{1}{2} \alpha'^2 (\log \epsilon)^2 D_\nu D_\nu D_\mu D_\mu T_R \\
&\quad + i \alpha'^2 (\log \epsilon)^2 D_\nu F_{\nu\mu R}^{(-)} D_\mu T_R, \\
A_\mu^{(-)} &= A_{\mu R}^{(-)} + \alpha' \log \epsilon D_\nu F_{\nu\mu R}^{(-)} \tag{5.15}
\end{aligned}$$

Note that we obtain the form (5.14) by a field redefinition which corresponds to a renormalization (5.15) from the two dimensional point of view.

6 Conclusions and Future Directions

In this paper we described the tachyon dynamics on the brane-antibrane by the method of the boundary string field theory. We constructed the world-sheet boundary action of the brane-antibrane system by using the boundary fermions. The remarkable point of this formalism is that for the special profile of the tachyon field the calculation of the tachyon potential and the tensions of the lower branes which are produced after the tachyon condensation can be performed exactly. From these calculations we confirmed the ‘descent relation’ of Non-BPS systems.

On the other hand in the case of including the all gauge fields it was difficult to calculate the exact effective potential except RR couplings. We found that the explicit form of the RR coupling in boundary string field theory can be represented by the superconnection. Furthermore we also took the transverse scalars into account and showed that Myers terms appear naturally.

We have also calculated several lower terms of the action of BSFT in the α' expansion. Further we discussed the general structure of the action and the result was consistent with the arguments on noncommutative solitons.

Our work raises some interesting questions and we hope to return to these in future work.

- As we have seen, the incorporation of one of the gauge field strength $F^{(+)}$ on a brane-antibrane system can be treated as a free theory and leads to the familiar noncommutative theory if the point-splitting regularization is employed. On the other hand, the exact treatment of the other field strength $F^{(-)}$ is found to be difficult. Then for brane-antibrane systems it seem to be essential to ask whether we can express this effect as a sort of a noncommutative theory.
- Our calculation here is performed assuming that the target space is flat. Then it is natural to ask what will happen to the tachyon physics if one considers a non-BPS D-brane system wrapping on a more complicated manifold such as a Calabi-Yau manifold. In such a case one should take world-sheet instantons into account. For example the discussion on their RR couplings will be modified and couplings may be expressed by some “stringy” Chern characters. A related question is how much the world-sheet supersymmetry has effects on the dynamics of tachyon condensation.
- One more interesting question is the physical meaning of the Myers terms which we have found for brane-antibrane systems and non-BPS D-branes in the framework of BSFT.

Acknowledgements

We would like to thank Y. Matsuo and K. Ohmori for useful discussions. The works of S.T. and T.T. were supported in part by JSPS Research Fellowships for Young Scientists.

Note added:

While preparing this paper for publication, we received the preprint [69] in which the world-sheet action for brane-antibrane system was given and the preprint [70] in which the BSFT for brane-antibrane system was discussed.

A Notation for Spinors and Some Formulas

Here we summarize our notation for spinors following [49] and after that we show some calculations which is needed for the derivation of the RR coupling in section 4.

The ten dimensional Γ -matrices $\Gamma_A{}^B$, ($A, B = 1, 2, \dots, 32$) are defined by the following Clifford algebra:

$$\{\Gamma^\mu, \Gamma^\nu\} = -2\eta^{\mu\nu}, \quad \eta^{\mu\nu} = \text{diag}(-1, 1, \dots, 1). \quad (\text{A.1})$$

Note that we distinguish spinor and adjoint spinor indices as subscripts and superscripts, respectively. The charge conjugation matrix C^{AB}, C_{AB}^{-1} , which obey the relations:

$$C\Gamma^\mu C^{-1} = -(\Gamma^\mu)^T, \quad (\text{A.2})$$

can raise or lower these spinor indices. Therefore we can omit the matrix C as

$$(\Gamma^\mu)_{AB} = C_{BC}^{-1}(\Gamma^\mu)_A{}^C, \quad (\Gamma^\mu)^{AB} = C^{AC}(\Gamma^\mu)_C{}^B. \quad (\text{A.3})$$

Note also from the above equations it is easy to see

$$C_{AB} = -C_{BA}, \quad (\Gamma^\mu)_{AB} = (\Gamma^\mu)_{BA}. \quad (\text{A.4})$$

We also define $(\Gamma_{11})_A{}^B$ as

$$\Gamma_{11} = \Gamma_0 \Gamma_1 \cdots \Gamma_9, \quad (\text{A.5})$$

and the chirality projection matrix P_\pm is defined by

$$P_\pm = \frac{1}{2}(1 \pm \Gamma_{11}). \quad (\text{A.6})$$

The matrix Γ_{11} satisfies the following identities

$$(\Gamma_{11})_{AB} = (\Gamma_{11})_{BA}, \quad (\Gamma_{11})^2 = 1, \quad \{\Gamma_{11}, \Gamma^\mu\} = 0. \quad (\text{A.7})$$

Before we will discuss the calculation of the RR couplings, let us now show some useful formulae. The first one is about the trace of Γ -matrices:

$$\text{Tr}[\Gamma^{\mu_0 \mu_1 \cdots \mu_p} \Gamma^{01 \cdots p}] = 32 (-1)^{\frac{p(p-1)}{2}} \epsilon^{\mu_0 \mu_1 \cdots \mu_p} \quad (0 \leq \mu_i \leq p), \quad (\text{A.8})$$

where $\Gamma^{\mu_0 \mu_1 \cdots \mu_p} = 1/p! (\Gamma^{\mu_0} \Gamma^{\mu_1} \cdots \Gamma^{\mu_p} - \Gamma^{\mu_1} \Gamma^{\mu_0} \cdots \Gamma^{\mu_p} + \cdots)$ denotes the antisymmetrized Γ -matrices. The second one is the famous relation between the Γ -matrices and the differential forms. More explicitly, a r -form in ten dimension:

$$C = \frac{1}{r!} C_{\mu_1 \mu_2 \cdots \mu_r} dx^{\mu_1} dx^{\mu_2} \cdots dx^{\mu_r}, \quad (\text{A.9})$$

corresponds to the following 32×32 matrix:

$$\hat{C} = \frac{1}{r!} C_{\mu_1 \mu_2 \cdots \mu_r} \Gamma^{\mu_1 \mu_2 \cdots \mu_r}. \quad (\text{A.10})$$

This correspondence preserves the multiplication as

$$: \hat{C}_1 \hat{C}_2 := \frac{1}{(r_1 + r_2)!} (C_1 \wedge C_2)_{\mu_1 \mu_2 \cdots \mu_{(r_1+r_2)}} \Gamma^{\mu_1 \mu_2 \cdots \mu_{(r_1+r_2)}}, \quad (\text{A.11})$$

where $:$ denotes the antisymmetrization.

Let us now turn to the derivation of the RR couplings. It involves the computations of the correlation functions on a disk whose boundary is on a Dp -brane. We assume its world-volume extends in the direction x^0, x^1, \cdots, x^p . Then it is easier to calculate

the correlation functions by performing T-duality transformation. This transformation is given with respect to the spin operators by

$$\begin{aligned} S_A &\rightarrow S_A \quad , \quad \tilde{S}_A \rightarrow M_A^{B} \tilde{S}_B, \\ M_A^{B} &= \begin{cases} \pm i \Gamma^0 \Gamma^1 \cdots \Gamma^p & (p = \text{even}) \\ \pm \Gamma^0 \Gamma^1 \cdots \Gamma^p \Gamma_{11} & (p = \text{odd}) \end{cases} \quad , \end{aligned} \quad (\text{A.12})$$

where S_A and \tilde{S}_B denote the left-moving and right-moving spin operators, respectively; the sign ambiguity \pm depends on the conventions and we choose the plus sign. The above rule can be derived by requiring that the OPE's of the left-moving fermions ψ^μ and spin operators S_A have the same structure as those of right-moving ones $\tilde{\psi}^\mu$, \tilde{S}_B after one performs the T-duality transformation. Using these facts, the RR couplings on both a non-BPS D-brane and a brane-antibrane system are summarized as the following form up to the overall normalization (see eq.(4.5) and (4.7)):

$$S = \sum_{r=0}^{p+1} \frac{1}{r!} K_{\mu_1 \mu_2 \cdots \mu_r} \text{Tr} [P_- \hat{C} M \Gamma^{\mu_1 \mu_2 \cdots \mu_r}], \quad (\text{A.13})$$

where $K_{\mu_1 \mu_2 \cdots \mu_r}$ ($0 \leq \mu_i \leq p$) is a r -form which depends on the field-strength and the tachyon field; \hat{C} denotes the RR-sector vertex as defined in eq.(4.2). If one takes the transverse scalars into account, one should also discuss $K_{\mu_1 \mu_2 \cdots \mu_r}$ for $\mu_i \geq p$. However such a case can also be treated similarly and we omit this. Then we can write down the RR couplings explicitly up to the overall normalization which is independent of r as follows:

$$S = \sum_{q,r=0}^{p+1} \frac{1}{q!r!} \delta_{p+1,q+r} \epsilon^{\mu_1 \cdots \mu_q \nu_1 \cdots \nu_r} C_{\mu_1 \cdots \mu_q} K_{\nu_1 \nu_2 \cdots \nu_r}, \quad (\text{A.14})$$

where we have used the formula (A.8). Finally these couplings are written in the language of the differential forms as

$$S = \int_{\Sigma_{(p+1)}} C \wedge K, \quad (\text{A.15})$$

where $\Sigma_{(p+1)}$ denotes the world-volume of the p -brane.
